SUMMARY
Adaptive learning object selection and sequencing is recognized as among the most interesting research questions in intelligent web-based education. In most intelligent learning systems that incorporate course sequencing techniques, learning object selection is based on a set of teaching rules according to the cognitive style or learning preferences of the learners. In spite of the fact that most of these rules are generic (i.e. domain independent), there are no well-defined and commonly accepted rules on how the learning objects should be selected and how they should be sequenced to make “instructional sense”. Moreover, in order to design highly adaptive learning systems a huge set of rules is required, since dependencies between educational characteristics of learning objects and learners are rather complex. In this paper, we address the learning object selection problem in intelligent learning systems proposing a methodology that instead of forcing an instructional designer to manually define the set of selection rules, it produces a decision model that mimics the way the designer decides, based on the observation of the designer’s reaction over a small-scale learning object selection case.

KEYWORDS: Adaptive Content Selection, Learning Objects, Intelligent Learning Systems

INTRODUCTION
The high rate of evolution of e-learning platforms implies that on the one hand, increasingly complex and dynamic web-based learning infrastructures need to be managed more efficiently, and on the other hand, new type of learning services and mechanisms need to be developed and provided. To meet the current needs, such services should satisfy a diverse range of requirements, as for example, personalization and adaptation (Dolog, Henze, Nejdl, Sintek, 2004). The field of computational intelligence in web-based education can contribute towards providing web-based technologies, methods and techniques for supporting teaching and learning in an intelligent way.
Learning object selection is the first step to adaptive navigation and adaptive course sequencing. Adaptive navigation seeks to present the learning objects associated with an on-line course in an optimized order, where the optimization criteria takes into consideration the learner’s background and performance on related learning objects (Brusilovsky, 1999), whereas adaptive course sequencing is defined as the process that selects learning objects from a digital repository and sequence them in a way which is appropriate for the targeted learning community or individuals (Knolmayer, 2003). Selection and sequencing is recognized as among the most interesting research questions in intelligent web-based education (McCalla, 2000; Dolog, Nejdl, 2003).

Although many types of intelligent learning systems are available, we can identify five key components which are common in most systems, namely, the student model, the expert model, the pedagogical module, the domain knowledge module, and the communication model. Figure 1 provides a view of the interactions between these modules.

In most intelligent learning systems that incorporate course sequencing techniques, the pedagogical module is responsible for setting the principles of content selection and instructional planning. The selection of content (in our case, learning objects) is based on a set of teaching rules according to the cognitive style or learning preferences of the learners (Brusilovsky, Vassileva, 2003). In spite of the fact that most of these rules are generic (i.e. domain independent), there are no well-defined and commonly accepted rules on how the learning objects should be selected and how they should be sequenced to make “instructional sense” (Mohan, Greer, McGalla, 2003). Moreover, in order to design highly adaptive learning systems a huge set of rules is required, since dependencies between educational characteristics of learning objects and learners are rather complex.

In this paper, we address the learning object selection problem in intelligent learning systems proposing a methodology that instead of forcing an instructional designer to manually define the set of selection rules; produces a decision model that mimics the way the designer decides, based on the observation of the designer’s reaction over a small-scale learning object selection problem.

In the next section we discuss the learning object selection process as part of automatic course sequencing. The third section discusses the filtering process of learning objects used for reduction of learning objects searching space and proposes metadata elements that can be used for learning object filtering. The fourth section presents a methodology for capturing expert’s decision model on learning objects selection and it constitutes the main contribution of this paper. Finally, we present experimental results of the proposed methodology by comparing the resulting learning objects selected by the proposed method with those selected by experts.
LEARNING OBJECT SELECTION IN AUTOMATIC COURSE SEQUENCING

In automatic course sequencing, the main idea is to generate a course suited to the needs of the learners. As described in the literature, two main approaches for automatic course sequencing have been identified (Brusilovsky, Vassileva, 2003): Adaptive Courseware Generation and Dynamic Courseware Generation.

In Adaptive Courseware Generation the goal is to generate an individualized course taking into account specific learning goals, as well as, the initial level of the student’s knowledge. The entire course is adaptively generated before presenting it to the learner, instead of generating a course incrementally, as in a traditional sequencing context. In Dynamic Courseware Generation on the other hand, the system observes the student progress during his interaction with the course and dynamically adapts the course according to the specific student needs and requirements. If the student’s performance does not meet the expectations, the course is dynamically re-planned. The benefit of this approach is that it applies as much adaptivity to an individual student as possible.

Both the above mentioned techniques employ a pre-filtering mechanism to generate a pool of learning objects that match the general content requirements. This pool can be generated from both distributed and local learning object repositories, provided that the appropriate access controls have been granted. The filtering process is based on general requirements such as characteristics of the language or the media of the targeted learning objects, as well as, on the use of ontologies for the domain in question (Domain Knowledge module). The result of the filtering process falls in a virtual pool of learning objects that will act as an input space for the content selector.

![Figure 1: Generalized Framework of Automatic Course Sequencing](image)

After the creation of the initial pool of learning objects, the content selection process is applied based on learner characteristics such as accessibility and competency characteristics or even historical information about related learning activities, included in the Student Model module. Figure 2 presents a generalized framework of the above mentioned course sequencing techniques that utilize filtering, content selection and instructional planning processes. In the next sections we will present some filtering elements based on the IEEE P1484.12.1 Learning Object Metadata (LOM) standard and we will analyze the methodology we propose for the content selection phase of automatic course sequencing.
LEARNING OBJECT FILTERING

The main goal of filtering is the reduction of the searching space. Learning Object Repositories often contain hundreds or thousands of learning objects, thus the selection process may require a significant computational time and effort. In most intelligent learning systems, learning object filtering is based either on the knowledge domain they cover or on the media type characteristics they contain (Kinshuk, Oppermann, Patel & Kashihare, 1999). In the IEEE LOM metadata model, there exist a number of elements covering requirements such as the subject, the language and the media type of the targeted learning object. Table 1 presents the IEEE LOM elements we have identified for each one of the above mentioned filtering categories and the conditions required.

Table 1: LOM elements for Learning Object filtering

Alternatively, filtering can be based on integration of the IEEE LOM metadata model elements and ontologies (Urban, Barriocanal, 2003), but those approaches assume that both the domain model and the learning objects themselves use the same ontology (Mohan, Greer, McGalla, 2003) and limit the filtering only to knowledge domain filtering.

LEARNING OBJECT SELECTION

Typically, the design of highly adaptive learning systems requires a huge set of rules, since dependencies between educational characteristics of learning objects and learners are rather complex. This complexity introduces several problems on the definition of the rules required (Wu, De Bra, 2001; Calvi & Cristea, 2002), namely:

- Inconsistency, when two or more rules are conflicting.
- Confluence, when two or more rules are equivalent.
- Insufficiency, when one or more rules required have not been defined.

The proposed methodology is based on an intelligent mechanism that tries to mimic an instructional designer’s decision model on the selection of learning objects. To do so, we have
designed a framework that attempts to construct a suitability function that maps learning object characteristics over learner characteristics and vice versa.

The main advantage of this method is that it requires less effort by the instructional designer, since instead of identifying a huge set of rules, only the designer’s selection from a small set of learning objects over a reference set of learners is needed. The machine learning technique will try then to discover the dependence between learning object and learner characteristics that produce the same selection of learning objects per learner as the instructional designer did.

The proposed methodology does not depend on the characteristics used for learning objects and learner modeling, thus can be used for extraction of even complex pedagogy-related dependences. It is obvious that since characteristics/requirements like the domain are used for filtering, the dependencies produced are quite generic, depending only on the educational characteristics of the content and the cognitive characteristics of the learner.

Figure 3 presents a graphical representation of the Selection Model Extraction Framework, consisting of three main steps:

- Step1: Modeling and Selection of Criteria
  The selection methodology is generic, independent of the learning object and the learner characteristics used for the selection. In our experiment, we used learning object characteristics derived from the IEEE LOM standard and learner characteristics derived from the IMS Global Learning Consortium Inc. Learner Information Package (LIP) specification. In Table 2 and 3 we have identified the LOM and LIP characteristics respectively, that can be used as an input space (set of selection criteria) to the learning object selector.
There exist many criteria affecting the decision of learning objects selection. Those criteria that lead to a straightforward exclusion of learning objects, such as the subject, the language and the media type, are used for filtering. The rest set of criteria such as the educational characteristics of learning objects are used for selection model extraction, since the dependencies of those criteria can model the pedagogy applied by the instructional designer, when selecting learning objects.

Those criteria, due to the complexity of interdependencies between them, are the ones that cannot be directly mapped to rules from the instructional designer. Thus an automatic extraction method, like the proposed one, is needed.

Table 3: LO Selector Input Space (Learner characteristics)

- Step2: Selection Model Extraction
After identifying the set of characteristics/criteria (step1) that will be used as the input space of the LO Selector, we try to extract for each learning object characteristic the expert’s suitability evaluation model over a reference set of LIP-based characterized learners. The input to this phase is the IEEE LOM characteristics of a reference set of learning objects, the IMS LIP characteristics of a reference set of learners and the suitability preference of an expert for each of the learning objects over the whole reference set of learners. The model extraction methodology has the following formulation:

Let us consider a set of learning objects, called \( A \), which is valued by a set of criteria \( g = (g_1, g_2, \ldots, g_n) \). The assessment model of the suitability of each learning object for a specific learner, leads to the aggregation of all criteria into a unique criterion that we call a suitability function \( S(g) = S(g_1, g_2, \ldots, g_n) \). We define the suitability function as an additive function of the form \( S(g) = \sum_{j=1}^{n} s_j(g_j) \), with the following additional notation:

- \( s_j(g_j) \): Marginal suitability of the ith selection criterion valued \( g_j \),
- \( S(g) \): Global suitability of a learning object.

The marginal suitability evaluation for the criterion \( g_i \) is calculated using the formula \( s_i(x) = a_i + b_i x \exp(-c_i x^2) \), where \( x \) is the corresponding value of the \( g_i \) learning object selection criterion. This formula produces, according to parameters \( a, b \) and \( c \) as well as the value space of each criterion, the main criteria forms, we have identified:

- Monotonic form: when the marginal suitability of a criterion is a monotonic function;
- Non monotonic form: when the marginal suitability of a criterion is a non-monotonic function.

The calculation of the optimal values of parameters \( a, b \) and \( c \) for each selection criterion is the subject of the Knowledge Model Extraction step.

Let us call \( P \) the strict preference relation and \( I \) the indifference relation. If \( S_{O_1} \) is the global suitability of a learning object \( O_1 \) and \( S_{O_2} \) is the global suitability of a learning object \( O_2 \), then the following properties generally hold for the suitability function \( S \):

\[
S_{O_1} > S_{O_2} \iff (O_1)P(O_2), \quad \text{and the relation } R = P \cup I \text{ is a weak order relation.}
\]

\[
S_{O_k} = S_{O_{k+1}} \iff (O_k)I(O_{k+1})
\]

The expert’s requested information then consists of the weak order \( R \) defined on \( A \) for several learner instances. Using the provided weak order relation \( R \) and based on the form definition of each learning object characteristic we can define the suitability differences \( \Delta = (\Delta_1, \Delta_2, \ldots, \Delta_{m-1}) \), where \( m \) is the number of learning objects in the reference set \( A \) and \( \Delta_k = S_{O_k} - S_{O_{k+1}} \geq 0 \) depending on the suitability relation of \((k)\) and \((k+1)\) preferred learning object for a specific learner of the reference set.

We can introduce an error function \( e \) for each suitability difference:

\[\Delta_k = S_{O_k} - S_{O_{k+1}} + e_k \geq 0\]

Using constrained optimization techniques, we can then solve the non-linear problem: Minimize \( \sum_{j=1}^{m-1} (e_j)^2 \)

Subject to the constraints:
\[ \Delta_j > 0 \quad \text{if } O_j > P_{j+1} \] for each one of the learners of the reference set.

\[ \Delta_j = 0 \quad \text{if } O_j = P_{j+1} \]

This optimization problem will lead to the calculation of the optimal values of the parameter a, b and c for each learning object selection criteria over the reference set of learners. Figure 4 presents the introduced error function, the suitability overestimation error as well as the suitability underestimation error \( e \), on the ordinal regression curve, which is the suitability ranking of the reference set of learning objects versus the approximation of the global suitability of each one of the learning objects in the reference set. Figure 5 presents a paradigm of marginal suitability extraction result (real expert’s model and the resulted approximation), when using Interactivity Type, Interactivity Level, Semantic Density and Difficulty as LO selection characteristics for a specific learner.

**Figure 4:** Ordinal Regression Curve (Ranking versus Global Suitability)

**Figure 5:** Marginal Suitability for a specific Learner (Continuous line represents the real expert’s model and the dashed one the resulted approximation)

- **Step3: Extrapolation**
  The purpose of this phase is to generalize the resulted marginal suitability model from the reference set of learners to all learners, by calculating the corresponding marginal suitability values for every combination of learner characteristics. This calculation is based on the interpolation of the marginal suitability values between the two closest instances of the
reference set of learners. Suppose that we have calculated the marginal suitability \( s_L^{L_1} \) and \( s_L^{L_2} \) of a criterion \( g_i \) matching the characteristics of learners \( L_1 \) and \( L_2 \) respectively. We can then calculate the corresponding marginal suitability value for another learner \( L \) using interpolation if the characteristics of learner \( L \) are mapped inside the polyhedron that the characteristics of learners \( L_1 \) and \( L_2 \) define, using the formula:

\[
 s_i\left(g_i^L\right) = s_i\left(g_i^{L_1}\right) + \frac{g_i^L - g_i^{L_1}}{g_i^{L_2} - g_i^{L_1}} \left[s_i\left(g_i^{L_2}\right) - s_i\left(g_i^{L_1}\right)\right], \text{ if } s_i\left(g_i^{L_1}\right) > s_i\left(g_i^L\right)
\]

Let \( C_i = [c_{i-}, c_i^+] \), \( i = 1, 2, \ldots n \) be the intervals in which the values of each criterion – for both learning object and learners – are found, then we call global suitability surface the space \( C = \times_{i=1}^{n} C_i \). The calculation of the global suitability over the above mentioned space is the addition of the marginal suitability surfaces for each of the learning object characteristics over the whole combination set of learner characteristics.

**EXPERIMENTAL RESULTS AND DISCUSSION**

In order to evaluate the total efficiency of the proposed methodology both on calculating the suitability on the training set of learning objects and on estimating the suitability of learning objects external from the reference set, we have designed an evaluation criterion, defined by:

\[
 \text{Success (\%) } = 100 \times \frac{\text{Correct Learning Objects Selected}}{n}
\]

where \( n \) is the number of the desired learning objects from the virtual pool that will act as input to the instructional planner. We assume that the number of desired learning objects is less than the total number of learning objects in the input space (learning objects pool) and that both the learning object metadata and the learner information metadata have normal distribution over the value space of each criterion.

Additionally, we have classified the learning objects, for both testing and estimation set, in two classes according to their aggregation level, since granularity is a parameter affecting the capability of an instructional designer to select learning content for a specific learner. The classification is based on the value space of the “General/Aggregation Level” element of the IEEE LOM standard. We present experimental results of the proposed methodology by comparing the resulting selected learning objects with those selected by experts. We have evaluated the success on both the training set of learning objects (Training Success) and on the suitability estimation of learning objects external from the reference set (Estimation Success). Figure 11 and 12 present average experimental results for learning objects with aggregation level 1 and 2 respectively.

If we consider that for one learner instance, the different combinations of learning objects, calculated as the multiplication of the value instances of characteristics presented in Table 2, lead to more than 900,000 learning objects, it is evident that it is almost unrealistic to assume that an instructional designer can manually define the full set of selection rules which correspond to the dependencies extracted by the proposed method and at the same time to avoid the inconsistencies, confluence and insufficiency of the produced selection rules.

The proposed methodology is capable of effectively extracting dependencies between learning object and learner characteristics affecting the decision of an instructional designer on the learning object selection problem.
More analysis on the results, presented in figures 11 and 12, shows that when the desired number of learning objects (n) is relatively small (less than 100), the selected learning objects by the extracted decision model are almost similar to those the instructional designer would select. On the other hand, when the desired number of learning objects is relatively large (about 500) the success of the selection is affected, but remains at acceptable level (about 90%).

Another parameter affecting the selection success is proved to be the granularity of learning objects. Granularity mainly affects the capability of an instructional designer to express selection preferences over learning objects. Learning objects with small aggregation level have bigger possibility of producing “gray” decision areas, where the instructional designer cannot decide which learning object matches most the cognitive style or learning preferences of a learner. In our experiments, learning objects with aggregation level 2, which can be small or even bigger collections of learning objects with aggregation level 1, appear to have less possibility of producing indifference relations, enabling to make secure decisions even for bigger desired number of learning objects (n=200).

CONCLUSIONS

In this paper we address the learning object selection problem in intelligent learning systems proposing a methodology that instead of forcing an instructional designer to manually define the set of selection rules; produces a decision model that mimics the way the designer decides, based on the observation of the designer’s reaction over a small-scale learning object selection problem.
